#### **TRIANGULATIONS**

- Types of triangulations
- Greedy triangulation
- Delaunay triangulation
- Triangulation of polygons

#### Types of triangulations

In geometry, a triangulation is a subdivision of a planar object into triangles. We will consider point-set triangulation and polygon triangulation.

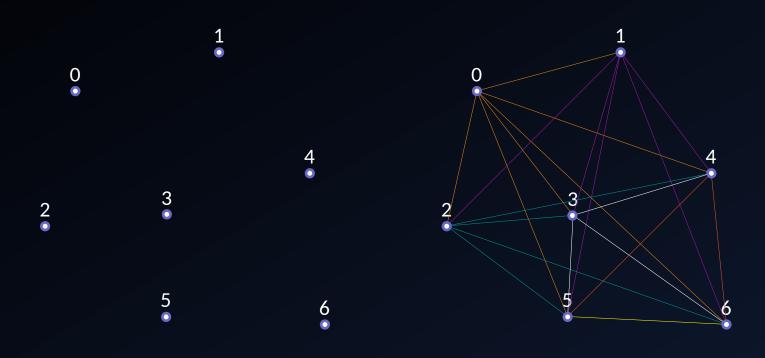

A point-set triangulation, i.e., a triangulation of a discrete set of points **P**, is a subdivision of the convex hull of the points into simplices such that any two simplices intersect in a common face of any dimension or not at all and such that the set of vertices of the simplices are contained in **P**.

There are many algorithms for point-set triangulation. The result of this type of the triangulation is at least the set of bounded edges or the set of triangles (TIN-model). The maximal number of edges for the set of N points is (3\*N-6).

The greedy triangulation is the simplest algorithm of the triangulation with complexity  $O(n^{2*}log(n))$ . During processing we do not reject any action have done before. The algorithm steps are below.

- 1. The square of the distance to other points is determined for each point.
- 2. The list of edges created in this way (Ro) is sorted by increasing edge length.
- 3. The first edge (with the minimum length) is recorded in the list of edges of the TIN model (RT).
- 4. For each edge of the set R<sub>0</sub>, an intersection test with the edges of the set R<sub>T</sub> is performed. If an edge does not intersect with the edges of the set R<sub>T</sub>, then it is added to the set R<sub>T</sub>. For N points, the process ends when the number of edges in the set R<sub>T</sub> is reached (3\*N-6) or after testing all edges of the set R<sub>0</sub>.
- 5. Triangles are formed on the set of RT edges by finding the edges incident to each point of the given set and adjacent edges to them. Each triangle in this model is presented in the form of (i,j,k) the indices of the initial points, which are the vertices of the triangle.

An example. STEP 1. Preparing list of sorted edges Ro.

| #  | EDGE  | LENGHT |
|----|-------|--------|
| 1  | 2 - 3 | 2.1    |
| 2  | 3 - 5 | 2.2    |
| 3  | 0 - 2 | 2.4    |
| 4  | 0 - 1 | 2.7    |
| 5  | 3 - 4 | 2.8    |
| 6  | 5 - 6 | 3.0    |
|    |       |        |
| 20 | 1 - 6 | 6.9    |
| 21 | 0 - 6 | 7.1    |

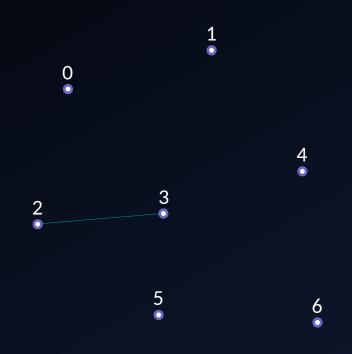

Set of points

Distances

Ro

An example. STEP 2. LOOP 1. Selecting edges from the Ro and adding to the RT.

| #  | EDGE  | LENGHT |
|----|-------|--------|

#### **DELAUNAY TRIANGULATION**

The Delaunay triangulation is a triangulation which is equivalent to the nerve of the cells in a Voronoi diagram, i.e., that triangulation of the convex hull of the points in the diagram in which every circumcircle of a triangle is an empty circle. Delaunay's triangulation is well balanced — its triangles are directed towards equilateral ones, and the system of triangles always has a convex hull.

#### **DELAUNAY TRIANGULATION**

Many algorithms for computing Delaunay triangulations rely on fast operations for detecting when a point is within a triangle's circumcircle and an efficient data structure for storing triangles and edges. In two dimensions, one way to detect if point **D** lies in the circumcircle of **A**, **B**, **C** is to evaluate the determinant:

$$\Delta = \begin{bmatrix} x_a & y_a & x_a^2 + y_a^2 & 1 \\ x_b & y_b & x_b^2 + y_b^2 & 1 \\ x_c & y_c & x_c^2 + y_c^2 & 1 \\ x_d & y_d & x_d^2 + y_d^2 & 1 \end{bmatrix} = \begin{bmatrix} x_a - x_d & y_a - y_d(x_a - x_d^2) & y_a - y_d^2 \\ x_b - x_d & y_b - y_d(x_b - x_d^2) & y_b - y_d^2 \\ x_c - x_d & y_c - y_d(x_c - x_d^2) & y_c - y_d^2 \end{bmatrix}$$

When **A**, **B**, **C** are sorted in a counterclockwise order, this determinant is positive only if **D** lies inside the circumcircle. The common algorithms are the following:

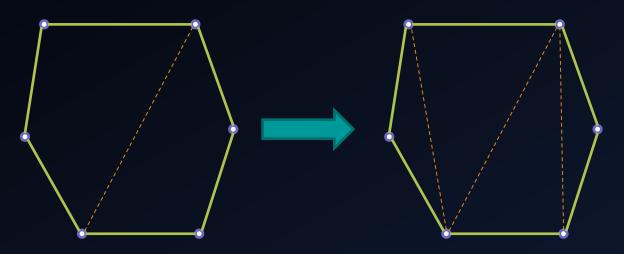

- Flip algorithms
- Incremental
- Divide and conquer
- Sweephull

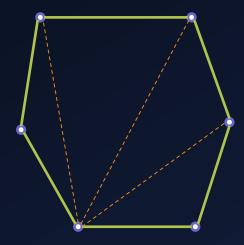

The task of polygon triangulation can be divided into three categories:

- 1. Triangulation of convex polygons.
- 2. Triangulation of non-convex polygons.
- 3. Triangulation of polygons with holes.

There are two methods for convex polygons triangulation:

- chord splitting into two polygons, and subsequent recursive splitting of each formed polygon until only triangles remain
- consecutive "cutting" of triangles by chords from one vertex

There are two methods for non-convex polygons triangulation:

- break it into convex polygons and triangulate with one of the algorithms described earlier
- apply the triangulation algorithm to a given non-convex polygon without dividing it into a convex one

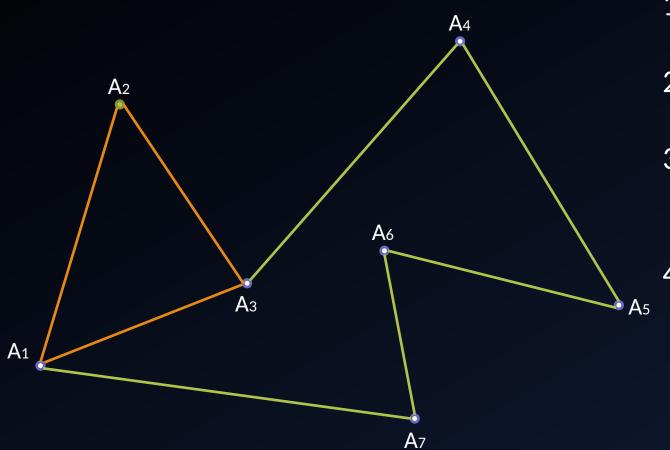

The simplest method of dividing a non-convex polygon into a convex one is clipping. Its algorithm is as follows.

- 1. Move the coordinate system to the first vertex of the polygon.
- 2. Rotate the coordinate system so that the X axis coincides with the edge of the polygon.
- 3. Find the sides of the polygon that lie below the X-axis and cut them off.
- 4. Go to the next vertex and repeat the algorithm recursively until only convex polygons remain.

Another method of triangulation of a non-convex polygon is the algorithm of sequential construction of triangles on three adjacent vertices with verification of the obtained result. First, we arrange all vertices of the polygon clockwise. Then the following algorithm can be used to construct the triangulation.

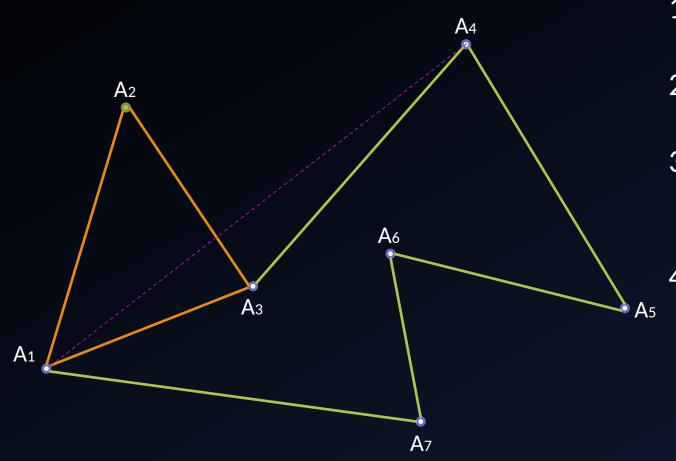

- 1. Take three consecutive vertices Ai, Ai+1, Ai+2.
- 2. Check if the vectors AiAi+2 and AiAi+1 form a right turn. Their cross-product must be positive.
- 3. Check if any of the remaining vertices are located in the triangle AiAi+1Ai+2.
- 4. If conditions 2 and 3 are met, we construct a triangle with the points AiAi+1Ai+2. We exclude the vertex Ai+1 from consideration. Next, we consider the triangle AiAi+2Ai+3.
- 5. If at least one of the conditions 2 or 3 is not met, then we proceed to consider vertices Ai+1, Ai+2, and Ai+3.
- 6. Repeat step 1 until only 3 vertices remain, forming the last triangle.

An example. STEP 1.

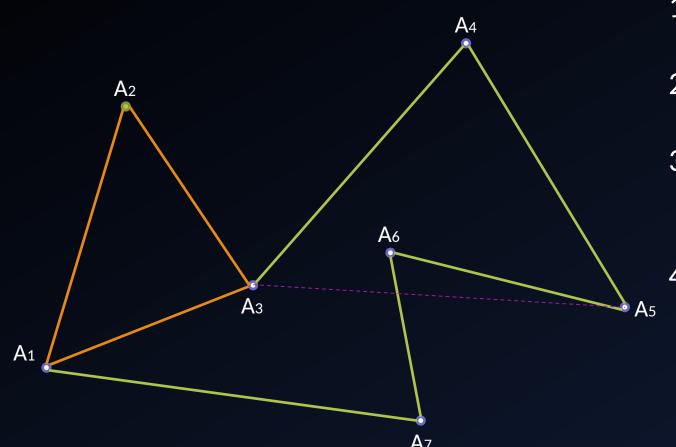

- 1. Take the first three points A1A2A3.
- 2. Check the cross-product sign of the vectors A<sub>1</sub>A<sub>2</sub> and A<sub>1</sub>A<sub>3</sub>.
- 3. Check if any of the remaining vertices are located in the triangle A<sub>1</sub>A<sub>2</sub>A<sub>3</sub>.
- 4. Both conditions are met, so we construct triangle A<sub>1</sub>A<sub>2</sub>A<sub>3</sub>. We exclude the vertex A<sub>2</sub> from consideration.

An example. STEP 2.

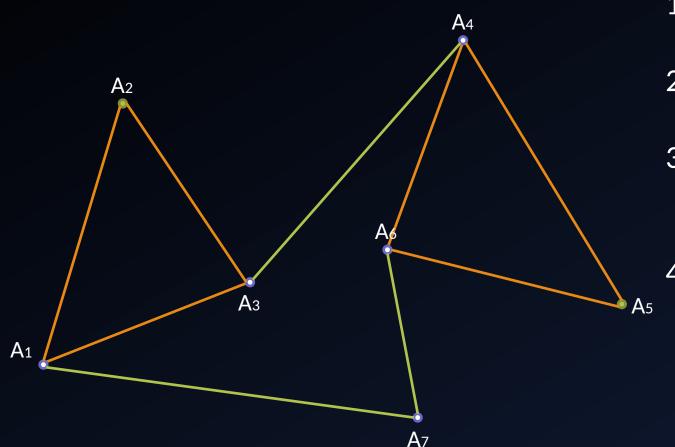

- 1. Take the next three points A1A3A4.
- 2. Check the cross-product sign of the vectors A<sub>1</sub>A<sub>3</sub> and A<sub>1</sub>A<sub>4</sub>.
- 3. Check if any of the remaining vertices are located in the triangle A<sub>1</sub>A<sub>3</sub>A<sub>4</sub>.
- 4. The first condition is not met, so we move to the next point.

An example. STEP 3.

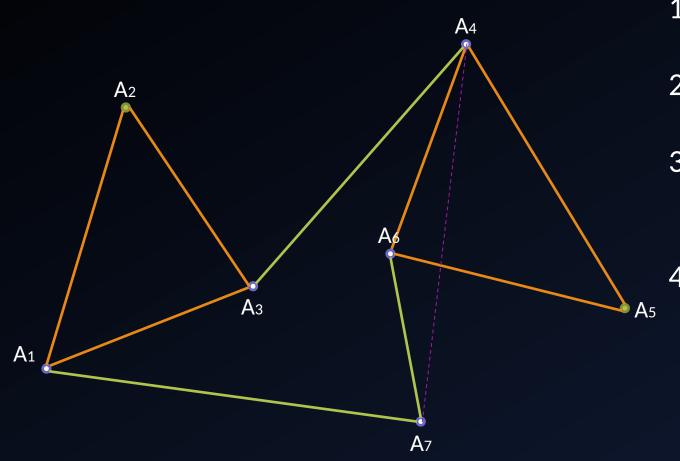

- 1. Take the next three points A3A4A5.
- 2. Check the cross-product sign of the vectors A<sub>3</sub>A<sub>4</sub> and A<sub>3</sub>A<sub>5</sub>.
- 3. Check if any of the remaining vertices are located in the triangle A<sub>3</sub>A<sub>4</sub>A<sub>5</sub>.
- 4. The second condition is not met, so we move to the next point.

An example. STEP 4.

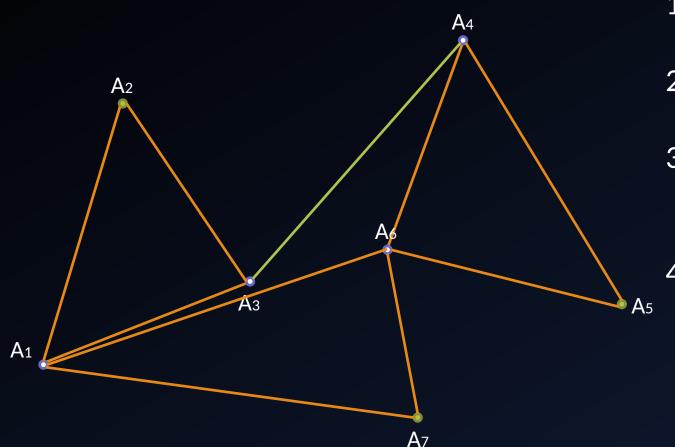

- 1. Take the next three points A4A5A6.
- 2. Check the cross-product sign of the vectors A<sub>4</sub>A<sub>5</sub> and A<sub>4</sub>A<sub>6</sub>.
- 3. Check if any of the remaining vertices are located in the triangle A<sub>4</sub>A<sub>5</sub>A<sub>6</sub>.
- 4. Both conditions are met, so we construct triangle A<sub>4</sub>A<sub>5</sub>A<sub>6</sub>. We exclude the vertex A<sub>5</sub> from consideration.

An example. STEP 5.

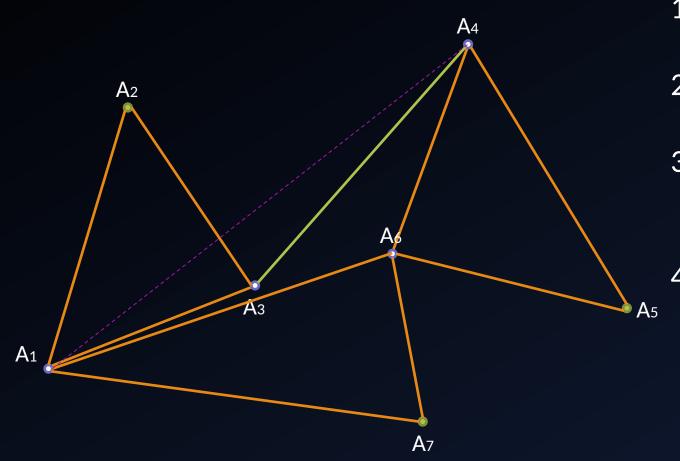

- 1. Take the next three points A4A6A7.
- 2. Check the cross-product sign of the vectors A4A6 and A4A7.
- 3. Check if any of the remaining vertices are located in the triangle A4A6A7.
- 4. The first condition is not met, so we move to the next point.

An example. STEP 6.

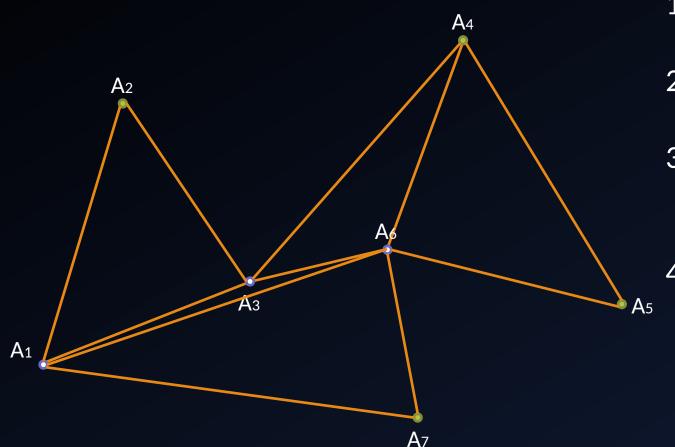

- 1. Take the next three points A6A7A1.
- 2. Check the cross-product sign of the vectors A6A7 and A6A1.
- 3. Check if any of the remaining vertices are located in the triangle A6A7A1.
- 4. Both conditions are met, so we construct triangle A6A7A1. We exclude the vertex A7 from consideration.

An example. STEP 7.

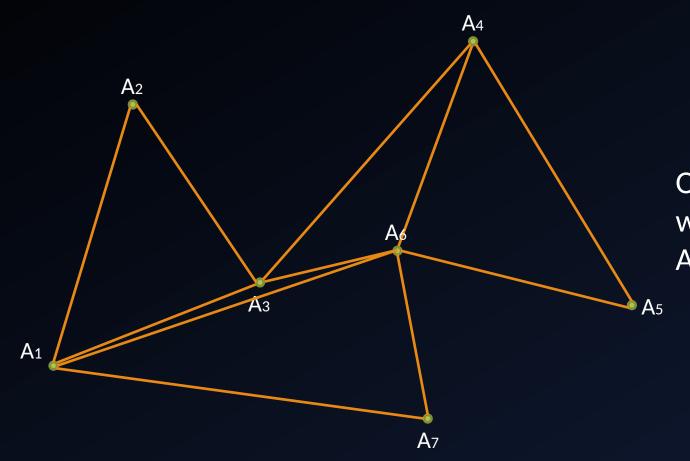

- 1. Take the next three points A1A3A4.
- 2. Check the cross-product sign of the vectors A<sub>1</sub>A<sub>3</sub> and A<sub>1</sub>A<sub>4</sub>.
- 3. Check if any of the remaining vertices are located in the triangle A<sub>1</sub>A<sub>3</sub>A<sub>4</sub>.
- 4. The first condition is not met, so we move to the next point.

An example. STEP 8.

- 1. Take the next three points A3A4A6.
- 2. Check the cross-product sign of the vectors A<sub>3</sub>A<sub>4</sub> and A<sub>3</sub>A<sub>6</sub>.
- 3. Check if any of the remaining vertices are located in the triangle A<sub>3</sub>A<sub>4</sub>A<sub>6</sub>.
- 4. Both conditions are met, so we construct triangle A<sub>3</sub>A<sub>4</sub>A<sub>6</sub>. We exclude the vertex A<sub>4</sub> from consideration.

An example. STEP 9.

Only three vertexes are left, so we construct the last triangle A3A6A1.

# Thank you!
